Abstract

In recent years Germany had to deal with demographical changes on his own territory, pointing an increasingly aging population and on the other hand with a low birth rate that could not normalize this trend. Family policy deals with these issues because one of its current goals is to raise birth rates and ensure and strengthen the position of women in the market. As a possible solution, the family policy sees it in the contribution of men to the share of parental leave. Therefore this diploma thesis will have this topic in the focus. The turning point for Germany and especially for fathers was the year 2007 when the so called “Elterngeld” was introduced with the goal to encourage men to take parental leave and support the woman with raising children.

Thanks to this fact that a man help a woman with an upbringing child and household, to women is given the possibility to return to the working environment earlier (at least for a half-time job). This partnership should ensure greater stability in the relationship and possibly ensuring next offspring that Germany necessarily needs. Since 2007 can be noticed interesting numbers of men entering the parental leave. Noteworthy is that one of the highest figures is reported by Saxony with Dresden and Leipzig. Since the man is now seen as one of possible solutions for improving the demographic structure, this work is also focused on Saxon fathers and on possible factors that influence their strong share. These factors will be in the practical part analyzed in detail and at the end of the work they will be evaluated whether the analyzed factors could be applied to other German regions and thus support the goal of family policy.
