

## Annotation

This bachelor dissertation deals with the problem of female incontinence. Theoretic part is devoted anatomy lower urinary tract, physiology discharging and detail described individual kinds of urinary incontinence, cause, treatment and prevention. In empiric part I felt to valorize how the urinary incontinence affects quality of life. I also tried to find out how long was the time interval before the patient finds the medical help and if there is enough awareness about the illness and its treatment. My research confirmed the fact that it is important to improve education and have enough information available about this problem in order to identify the early symptoms and eliminate negative notions. The most important is to improve understanding of women's feelings and needs and to (decrease) eliminate the embarrassment related to this problem.
