

We wanted to describe the situation of sibling incest in the population of the Czech men and women in the age between 18-30 years old. The questionnaire of 21 items was created for this purpose. The questionnaire was located to the Internet and we distributed it to 9 secondary schools as well. Overall we acquired 1599 completed questionnaires. 89 of the informants had an experience with the sibling incest. 71 of them were victims, 18 were perpetrators. We found out, that the most common sexual activity was touching and masturbation, in 1/3 cases vaginal intercourse was made. The most common perpetrators was the older brother, the most common victim was the younger sister. The average age difference between siblings was 4,7 year. The most of the victims report negative influence of this act (f.e. depression, anxiety, somatic problems, nightmares). These negative influences were temporary in the most of the cases.
