

In spite of increasing interest at the problematic of memory, the field of memory and logopedia is "tabula rasa". Therefore I try to describe general view of memory at adult people with impaired communication ability in my paper „Memory achievement at adult people with impaired communication ability" . The aim of this work is to map memory function of these people with memory test made by myself. This test is focused on adult people with impaired communication ability and also on healthy adult people which work as a control sample. I also presume that thist test can fill up a blank in test materials for speech therapist and also work as a material for training.
