

Diabetes mellitus type 2 is a disease occurring mostly over the age of 40 years.

In recent years, however, increasingly more often in younger populations , often even adolescents and children. The team is also related to the increasing prevalence of pregnant women diagnosed with

pregestačným type 2 diabetes . Material fact is worsening of pregnancies among these women. The incidence of congenital malformations is 2 - 3 times higher than the normal population . prevalence of sudden

intrauterine death is approximately four times higher . Perinatal mortality is comparable in both types of diabetes (2.6% of type 1 diabetes vs.3 , 7 % for type 2 diabetes ) but causes leading to

fetal death are different. In Type 1 diabetes is the leading cause of perinatal mortality

severe malformation of the fetus and complications related to prematurity . In type 2 diabetes

dominated by sudden intrauterine fetal death . From these facts shows how important it is to you

earliest detection of the disease , the importance of preconception care with emphasis on planning

Parenting and provide adequate prenatal care.
