

## Annotation

My bachelor thesis deals with an impact of diabetes mellitus, type 2 on patients` QoL.

The main focus of this thesis is on the individualized perception of QoL. This method of QoL measurement does not determine criteria beforehand, but is based on the subjective perceptions of respondents, what he/she considers important. This thesis surveys both generic and diabetes dependant QoL. Not only was it my intention to find life domains of patients, but also evaluate the impact and importance ratings of the particular life domain, using the SEIQoL method.

The focal point of the thesis is an explorative investigation in the internal sickbed department of the hospital in Nový Bydžov. The aim of the thesis is not only to compare the diabetes mellitus dependent QoL of insulin-treated patients versus patients treated by perioral antidiabetic drugs (PAD), but also evaluate the overall difference of QoL between life domains indicated by patients on a thermometer scale and my calculation based on acquired data.
