

The main purpose of this study is to create a concept of a prediction diagnostic method for psychological and behavioral prediction of sexually offending acts. The target of this complex analytical method is to classify and differentiate chosen predictors in sexual aggressors from statistical average values and to compare this unique model with the profile of an individual, who is prone to pathological behaviour, prior to its manifestation. To be able to find the "causal and comorbidity nexus for early prediction", a profile of a sexual serial killer has been used. The study is built on a hypothesis, that it is possible to anticipate this complex pathological profile with features of violence and sadistic aggression in the sexual disruptive person before a criminal act is committed. This prediction is based on comparison of 112 predictors in 49 sexual serial killers (experimental group), which has revealed several equal components (explicit and implicit comorbid nexus). To what degree and how qualified I have performed this task is partially reflected both in the body of the work and in the final summary.
