

The effect of a single treatment of the levator ani muscle and the coccyx on the reduction of pain and discomfort during sexual intercourse was studied in a group of ten female patients with an established diagnosis of dyspareunia. The influence of a single treatment on the pain of the coccyx, paracoccygeal region and other functional disorders in connection with this diagnosis was also observed. Another part of this research was the effect of a single treatment on the changes in the observation of other possible sexual dysfunctions. The presence of psychiatric disorders was also determined. Undertaking the therapy has led into the reduction of pain and the discomfort of the sexual intercourse, the reduction of pain of the coccyx and the paracoccygeal region and to the reduction of the occurrence of functional disorders. A minor improvement in sexual functions was also observed.
