

The thesis deals with prevention and appearance of complications with the patients after a stroke. These patients are endangered by many complications, connected not only with the disease itself but also with their health before hospitalization.

For the purposes of my thesis, I chose a qualitative method. It is a specific method which uses given problem in details and gives a complex perspective of all examined criteria. I collected the data with the help of example studies which I examined further on and compared it.

The results of my research show that the most frequent complications endanger the chosen patients. Further on I deal with interventions with which I intentionally prevented the complications. In the last part I evaluate the results of preventive arrangements about how the respondents perceived my treatment care.
