

The aim of my degree work has been the verification of screening methods. The examination is based on emotional traumatization of the juvenile subject. As far as screening examination is concerned the method of Hardin and Peterson has been used (L.W.Peterson, M.E.Hardin, 1997). Twenty children (including boys as well as girls) were chosen to undergo the research. Children haven't been chosen randomly but with the disposition to risk factor.

As a matter of fact conditions of the method were observed and according to the instructions every child drew a human body, on which the presence of certain indicators were identified. The amount of indicators were counted together. As a result of the research the outcome was classified into 3 groups (0-2 without a danger, 3-5 low danger, 6 and more high danger).

90% of observed children has been without any risk at all. 10% of children pictures were evaluated as a low danger ones. In that case a chat with that child has been done and that may have confirmed the analysis.

In conclusion I may claim that the method I have chosen is suitable for screening examination. Even though it is very fast and accurate there is one point I would like to reproach – children are chosen according to teacher which may be a problem. Therefore my suggestion is to realise this examination in all groups with every children. By estimate conclusions were phrased this recommendation in area of sociality, school and family.
