Changes of voiding regimen in patients before and after kidney transplantation

The purpose of my work is to find out, whether patients before kidney transplantation felt some kinds of voiding disorders taking into account their basic disease. I have focused the main part in my work into voiding disorders after kidney transplantation. In the theoretic part I have digestedly described kidney diseases that led to renal failure, treatment possibilities and related complications. Furthermore, my work is dealing with problems in patients with chronic disease generally, because dialyzed patients surely could be placed in this group.

In the empirical part I tried to find out and characterize subjective perception of complaints with urination by a questionnaire investigation. I have used a standardized and modified questionnaire KHQ, in part, my own questionnaire to verify the condition of urination and diuresis before kidney transplantation. For my work I have choused patients, who had been oliguric or anuric before kidney transplantation. I got a 42 responders from the total 59 addressed patiens.

The target of this inquiry was to find out whether patients can perceive the voiding changes and possible new problems with urination in everyday activities, personal relationships, emotions and in physical and social area, which may be affected by the voiding disorders. It was emphasized on that how is alone patient felling, living and evaluating his voiding disorders.

In the end of the work I'm comparing the ascertained problems with supposed condition and summarizing the results that concern perceptions of changes in urination before and after kidney transplantation.
