

The authors deal with Sexual Behavior in Eating Disorders, especially in patients with Bulimia Nervosa. In patients with Eating Disorders we observe distortion of body image and negative affective evaluation of one's own body and personality, like a common symptom. We assumed, the symptoms may influence bulimic patient's sexuality and sexual behavior. On the other side, we assumed the specific psychosexual development, sexual experiences in childhood and personality features in bulimic patients can also be a reason of Eating Disorder. Our question is: What is the sexuality and sexual behavior in bulimic patients? We present our research on women, who are nowadays treated for Bulimia Nervosa. We specially focus on Coital Debut, Masturbation, Sexual Activities with a Sexual Partner, Sexual Excitement, Sexual Disorders, Number of Sexual Partners, Sexual Orientation and Sexual Satisfaction. In comparison to normal Czech population in age 18-29 years, we observe these differences. Patients have had a first relationship at higher age, they also have had a higher number of relationships and higher number of sexual partners. More bulimic patients have had experiences with masturbation and most of them are still masturbating. Patients do not have orgasm during the sexual intercourse so often as normal population and more patients pretend orgasm during the sexual intercourse. More patients with bulimia nervosa had in the past and have in the present sexual disorder. More women with bulimia nervosa had a homosexual intercourse. More patients with bulimia nervosa was forced to have a sexual intercourse. Most of them is not sexually satisfied. We hope these results of our research will help to understand Sexuality of Women with Bulimia Nervosa.
