

The dissertation followed 3 research goals: to compare the availability of controlled physical activities in children with mental, hearing, visual disability in selected regions of the EU countries (South Bohemia-Czech Republic, Plovdiv-Bulgaria, Primorska-Slovenia, West Midlands-UK), then in experimental investigation in South Bohemia to monitor indicators of physical health in samples of children with named disabilities, and in same children to monitor indicators of psychosocial health. Analytical research investigations related to availability of controlled movement activities included children aged 8-15 years with researched disabilities, registered in the school systems of analysed regions of EU countries (N=12073 children, 6355 males, 5718 females). In followed experimental investigation in South Bohemia 180 children participated (90 males, 90 females) aged 8 - 15 years, were divided in samples according researched disabilities. Evaluation of the data and their statistic interpretation verified the hypotheses. Research results have shown that children with observed types of disabilities can achieve positive effects in anthropometric indicators of training under the influence of controlled physical activities. Research results present also benefits for the social rehabilitation of children with disability in the problematic of reducing fearful behaviour symptoms and in increasing of independent behaviour
