Self recognition is highly discussed topic in cognitive sciences. Experiments on a level of behavioral (mirror test, reference tests of body parts using) show that animals usually are able to realize parts of their own body. There are several experimental evidence among cetaceans of this kind that proved that they are conscious of their own body parts (self awareness). There are also many other complex cognitive skills that can be predisposition to self recognition or that can prove that cetaceans are conscious of their own mind (self consciousness).
