Abstract

The present thesis examines the influence of Czech nouns frequency features on their acquisition by non-native speakers. The first theoretical part summarizes the ongoing discussion regarding the importance of frequency for the entrenchment of grammatical categories in one’s mind as outlined by cognitive and psycho-linguists abroad. The second introduces the research methodology, collection method and annotation of 20 lemmas obtained from non-native Czech speaker corpus CzeSL-SGT. Subsequently, an analysis of selected nouns is carried out with regard to their grammatical profiles (comprising two or three most frequent case forms as found in SYN2015). Based on its results, the production of non-native speakers shows a tendency to follow grammatical profiles as demonstrated by high correspondence of frequency features of nouns on the one hand and by low error rate in morphology of most frequent forms on the other. Additionally, cases where lower rate does not correspond to the above mentioned model can be explained using type frequency, i.e. the productivity of particular declension models having simultaneously more far-reaching effect, and higher relevance of nominative as the default form for non-native speakers.
