

1. Abstract

Tephrosia longifolia subsp. *moravica* is a critically endangered endemic with only a few recently known localities in Moravia and Slovakia. This thesis contains a comprehensive survey of all known localities and is concerned with the size and development of the recent Moravian populations in more detail. In addition, it provides the information about the taxon's phenology, preferred plant associations, possibilities of reinforcement of the current populations, and contains suggestions for suitable management of the Moravian localities.
