

## Annotation

This bachelor work is about complete evaluation of death from the medical first-aid service worker's point of view. It concentrates on determination of feelings hierarchy of the medical first – aid service worker during meeting with the death, during patient's death subsiding, furthermore it concentrates on aggression as a reaction to the death from the survivors' side and on the medical first – aid service workers' attitude towards their own mortality.

A qualitative part and a quantitative anonymous experimental part are the ground of this work. I evaluated two different types of death, that have an influence on mental state of the medical first-aid workers, by means of two case studies in the qualitative part. I made evaluation immediately after an acute stressful situation and later on after about a half of a year. I evaluated perception of death by the first – aid service worker in the quantitative experimental part by means of an anonymous question-form. My testing sample consists of these first – aid service workers – namely a driver, a driver – rescuer, a medical rescue worker, a nurse with PPS – ARIP, IP. Within the framework of my bachelor work I addressed 110 respondents who gave me back 108 properly filled question-forms.
