

## Abstract

This thesis aimed to streamline the method of the preparation of high entropy carbides. The simplification of synthesis and expense reduction were achieved using sol-gel method instead of using commercial starting powders. As precursors of transition metals, the chlorides ( $\text{TiCl}_3$ ,  $\text{TaCl}_4$ ,  $\text{HfCl}_4$  and  $\text{NbCl}_5$ ) and chlor-oxide ( $\text{ZrOCl}_2$ ) were used. The source of carbon was citric acid. All reactants were mixed in solution and dried to gel. The pyrolysis at  $800\text{ }^\circ\text{C}$  afterwards leads to creation of the amorphous carbon, which embedded the transition metal oxide nanoparticles. The carbothermal synthesis was completed in *Spark plasma sintering* device at  $1400\text{ }^\circ\text{C}$ ,  $1600\text{ }^\circ\text{C}$  and  $1900\text{ }^\circ\text{C}$ . Formation of high entropy carbide phase was achieved at  $1600\text{ }^\circ\text{C}$ , which is almost  $400\text{ }^\circ\text{C}$  less than previously reported in literature. Intermediate and final products were characterized with powder X-Ray diffraction, scanning electron microscopy and products, in addition, were characterized with transmission electron microscopy and elements mapping.

**Key words:** high entropy carbides, carbothermal reduction, high temperature ceramics, sol-gel method,
