

Abstract:

This work introduces and compares some basic facts about recultivation and alternative methods of restoration, such as revitalization and natural succession. Recultivation is the way of quick revegetation, but it's expensive and in many cases contraproductive considering biodiversity of recultivated sites. Whereas, approaches based on principles of ecological restoration have many positives. They can create much valuable landscape structures and ecosystems than recultivation, and they enhance biodiversity and conservation of rare species.
