Title           The return of a person after lower limb amputation into society.  
of  
thesis:

Aim            Determine how the patient perceives care in terms of  
of              physiotherapy and psychology at various stages:

work:

- hase I. - prior to rehabilitation
- hase II. - At the end of rehabilitation
- hase III. - At intervals after the return back home

Metho        The task is concieved as a methodological study is concerned  
d:            with the return of a person into society after lower limb  
              amputation.

The processing is based on a method of observation of patients in a rehabilitation clinic. The method was further extended by evaluating feedback from patients.

The method of auto-detection, which is based on assesment, communication with the patient and practical daily diagnosis of the progress of rehabilitation is combined with a method of questionnaire to verify the feedback from the patient.

The aim of the feedback is to provide personal information on their own, individual – specific perspective of each individual patient „That would be reliable“.

The combination of both methods would be to exclude the distortion of results gained by one individual – therapist.

**Results:** To improve the integration of the patient with lower limb amputation into society, more emphasis should be given to the patient's psyche and methodological guidance through all phases of convalescence.

On the basis of these facts, it is asserted that the consulted hypothesis is confirmed.

I came to the conclusion that the re-integration was as quickly as possible, should be in the current health care and subsequent care of an individual greater emphasis on intensive work with the patient's psyche and methodological guidance through each stage of convalescence.

**The Key words:** Amputation, amputation stump, prosthesis, psyche, rehabilitation, prosthetics, phantom pain
