

## Abstract

This bachelor thesis deals with the characteristic of the locality "Obora Hvězda" in the city of Prague. In the first part current knowledge of the geology and history of the locality is summarized and its biological features described. This part is completed with the author's original photographs from the field and from the palaeontological collections of the National Muzeum. The work is aimed namely on public who could use it to expand their knowledge on the proposed educational natural trail for children. This new trail is dealt with in the concluding part of the submitted thesis; it is assumed to replace the current one which does not capture children's interest adequately due to it being too long and accompanied with rather complicated verbal descriptions. The thesis includes two newly elaborated information boards as an example of the rationale of the new trail project. The emphasis is on graphical presentation using brief texts conveying the important message as well as illustrations and photographs.
